Abstract

Recently, the need to contribute to the evaluation of the scientific, social, and political impact of Social Sciences and Humanities (SSH) research has become a demand of policy makers and society. The international scientific community has made significant advances that have transformed the impact of evaluation landscape. This article reviews the existing scientific knowledge on evaluation tools and techniques that are applied to assess the scientific impact of SSH research; the changing structure of social and political impacts of SSH research is investigated based on an overarching research question: to what extent do scholars attempt to apply methods, instruments, and approaches that take into account the distinctive features of SSH? The review also includes examples of European Union (EU) projects that demonstrate these impacts. This article culminates in a discussion of the development of the assessment of different impacts and identifies limitations, and areas and topics to explore in the future.

Key words: social sciences; humanities; impact assessment; evaluation.

1. Introduction

A key concern of contemporary research policies is to demonstrate the ‘impact’ of research, or the value that public investment in research generates for increasing scientific competitiveness and excellence of the country, wealth creation, productivity, and social well-being. Impact is often understood as a change that research outcomes produce upon academic activities, the economy, and society at large. However, speaking of ‘attributable change’ poses some problems, such as finding adequate tools and methods to measure impact, the time lag between the effect produced and the research activities that are supposed to have generated it, as well as the problem of disentangling the extent to which the research results were the sole or most significant causes of the effect produced.

In addition to these well-known shortcomings, another problem is the different modes by which disciplinary fields are likely to impact academic communities, the economy, and society. This is especially true for Social Sciences and Humanities (SSH) because of their organizational and epistemic characteristics, and the type of outcomes that differentiate them from the Science, Technology, Engineering, and Mathematics (STEM) disciplines (Whitley 2000; Bastow, Dunleavy and Tinkler 2014).

The research questions the article addresses are: How far does impact assessment in SSH attempt to apply methods, instruments and approaches that take into account the distinctive features of SSH? and: Are the dominant (STEM) perspectives of impact evaluation applicable to SSH research? We investigate these questions through the review of the literature, which sheds light on the state of the art of knowledge production in the field, and allows us to understand what is still missing in the analysis and therefore the relevant gaps that need to be addressed.

In the review, we articulate the concept of impact by distinguishing between the different structures of scientific, social, and political impacts of SSH research. The assumption is that unpacking the concept of impact should allow us to improve knowledge of the different types of changes that are likely to be produced, and hence to assess them in a more robust manner.

The article is organized as follows: Section 2 explains how we frame the systematic literature review to identify the key themes and dimensions emerging in SSH evaluation; Section 3 presents the method and data used for the review; Sections 4–6 present the review’s findings and focus on three types of research impact: scientific, social, and political; Section 7 discusses advances in knowledge of each type of impact, connections between these impacts, and their limitations. Section 8 presents the article’s conclusions, which centre on the need to advance knowledge of how to understand, measure, and assess SSH research impacts.

2. Framework and method of the literature review

This article aims to deepen our knowledge of specific features of assessing the impact of SSH research in three respects. First, it highlights the relationship between science and society and its bearing on research conduct and evaluation. In recent years, top-down political demand has led publicly funded research agencies to increasingly account for the scientific and broader societal impacts of the research that they support, which has in turn required researchers and research institutions to provide evidence of these impacts. This has been accompanied by bottom-up demands from academic researchers and research users (for example, within civil society) to articulate the value of research for society (Beck 1992).

Secondly, the review emphasizes the relevance within the literature of discipline-specific research evaluation. At national and cross-national levels, research evaluation and research policy tends to be designed from the perspective of the life sciences and the natural sciences, with SSH research commonly an afterthought (Donovan 2005). To bridge the gap between science and society, traditional research evaluation schemes are being reconsidered and reformed (Arnold 2004) in ways that make the scientific and public value of SSH research potentially more visible, and to this end non-standard research assessment tools have been developed and applied to evaluating the impact of SSH research.

Thirdly, although a dedicated literature exists on research evaluation, other relevant pockets of literature are focused within an extensive range of SSH journals, as well as within books, chapters, and grey literature. This article reviews these diverse contributions to the scholarly literature on the evaluation of the scientific, social, and political impact of SSH research.

2.1 Motivations driving the investigation

As discussed above, policy makers justify the investment of public resources in R&D in terms of scientific advances that are likely to stimulate knowledge production (scientific impact). Wider impacts include the possibility of providing solutions to perennial policy problems (policy impact), and creating interventions to improve societal challenges (societal impact). Policy makers therefore want to understand (define, measure, and capture) these effects to be sure that they are using public funding to sustain ‘good science’. However, the policy makers’ perspective of ‘good science’ is not aligned with what scholars in all fields consider to be good science, since their main preoccupations are often with the robustness of the methods used, the reliability of tests and analysis, and the integrity of the research effort (Guetzkow, Lamont and Mallard 2004).

This divide is even more important for SSH due to the distinctive features that differentiate it from natural sciences. For example, several authors characterize SSH according to organizational and institutional perspectives (Whitley 2000), the likelihood of SSH to be local or internationally oriented (Forbes and Abrams 2004), and reflexivity and the appreciation of novel research efforts (Guetzkow et al. 2004; Weingart and Schwechheimer 2007; Ochsner et al. 2013). Other recent pieces of work (Bod 2013; Molas-Gallart 2015) have pointed out that SSH is more interested in new approaches—which are the essence of originality, rather than in new theories or findings; SSH are reflexive and non-cumulative sciences, contrary to the normative and cumulative structure of natural sciences, so judgements on the value of research can vary depending on the existing different schools of thought (Weingart and Schwechheimer 2007; Ochsner, Hug and Daniel 2016). These characteristics have distinct effects on impact assessment. Despite the fact that a distinctive feature of SSH scholarship is a commitment to developing research for the good of society, the interest of scholars is often not oriented towards producing ‘usable’ results (Berube 2002; Benneworth 2015), but to influence and orient society, to maintain cultural heritage, and to create capabilities of self-understanding in different contexts (Nussbaum 2010; Ochsner et al. 2013; Small 2013). Thus, scholars highlight that SSH impact cannot be assessed as ‘return on investment’ (Weingart 2007). It therefore follows that looking for similarities and normative solutions to assess SSH research impact would not produce reliable results because it clashes with the internal diversity of the disciplines (Kuhlmann 1998).

2.2 Distinguishing between impacts

The article addresses three different types of impact (scientific, social, and political) assuming that this distinction will allow a better understanding of how SSH research is likely to generate change in science and in society.

Scientific impact is commonly defined as a change in research, which breaks the dominant paradigm and influences future research investigations. In fact, ‘there is a distinction between “academic
impact” that is understood as the intellectual contribution to a person’s field of study within academia and the “external socioeconomic impact” beyond academia (Penfield et al. 2014: 21). However, in SSH the identification of ‘dominant paradigms’ is difficult due to the co-existence of competing paradigms and the difficulty in finding a common definition of what research quality means (Ochner, Hug and Daniel 2016), and finding common criteria to assess it (Guetzkow et al. 2004). Thus, scientific impact in SSH research is related to the capacity of founding new schools of thought and influencing future research in the field. It is not important for new schools to become dominant within the field: in SSH, different schools can co-exist; what is important is the fact that the new schools are producing research that follows a different approach.

The conceptualization of the social impact of research remains an ongoing effort. Flecha (2014) makes the distinction between scientific impact, dissemination, political impact and social impact, and argues that social impact can be understood as the culmination of the prior three stages of research. Therefore, the social impact of research occurs when published and disseminated results, which have been transferred into a policy or an NGO-led initiative, produce improvements in relation to the stated goals of society. However, a major problem in the literature is the lack of consensus on the meaning of the word ‘social’. In some publications, a broad spectrum of social impact areas is listed: human rights, social cohesion, economic cohesion, employment, human capital formation, public health and safety, social protection and social services, livable communities, culture, consumer interests, security, governance, international cooperation, role of SMEs, lessons learnt and success stories (European Commission, 2005). At the other end of the social impact spectrum, the social impact domain is limited to a few items that pertain to the living conditions of people: welfare, well-being, and quality of life, customs and habits of life, i.e. consumption, work, sexuality, sports, and food (Godin and Doré 2005). Sometimes the terms ‘social’ and ‘societal’ are interchangeable (Bornmann 2013: 218); in other cases, a distinction is made.

The assessment of the political impact of research as a separate from social impact has gained momentum in Europe, especially when investigating the relationships between science and policy and how to enhance the impact of the results of research on the policy process. Political impact of research occurs when knowledge is transferred, that is, when decision makers and/or social actors employ the published and disseminated results as the basis for their policies and/or actions (Flecha 2014). Although it significantly overlaps with the concept of social impact, its specific features relate to the fact that it addresses transformations that are produced in policy development and in the policy process (motivations and rationales, policy design, policy implementation, and policy assessment). For this reason, the article addresses political impact separately from social impact, taking into account both the macro-politics of dealing with large-scale decisions affecting the solution of complex problems, and policy related to micro-scale implementation of specific intervention techniques.

3. Method and data
The three types of impact the article addresses produce different orders of change within science and society. SSH research generates scientific impact when it influences the production of further research outputs following new approaches for analysis or based on new results. Changes related to social impact affect the cultural, economic, and social life of individuals, organizations, and institutions. Political impact incorporates the contents of research into political decisions, and motivations and rationales for political action and priority setting.

In this review, we aim to understand the way in which the aforementioned changes occur, and how far new avenues, such as the importance of researchers engaging and interacting with society, were explored. To enable this, we use the analytical framework of critical communicative methodology (CCM) proposed by Gómez and colleagues (2011), which considers people as transformative social agents who are able to produce changes in the existing order. CCM considers that change from research is likely to occur when ‘lifeworld is incorporated into the research process from the beginning to end’ (p. 238). Two analytical dimensions characterize the CCM methodology, namely, the exclusionary one and the transformative one. The former refers to the barriers impeding non-academic individuals and groups from participating or from enjoining benefits; the latter dimension refers to the actions that help to overcome the barriers and produce a change in a given social situation (Gómez, Puigvert and Flecha 2011). Thus the analysis presents evidence of what the literature on the impact of SSH research found to be factors that promoted or inhibited the successful scientific, social, and political impact of research.

Because the fields investigated have very different types of research outputs, the article used the following sources for data collection:

- Journal articles: the literature search was conducted using the Web of Science (WoS) and SCOPUS databases;
- Books, reports, and working papers;
- CORDIS database: exploration of EU FP6 and EU FP7 projects (2006–12);
- The EU FP7 Flash-it project\(^1\) as a source for relevant research reports;
- Web searches, e.g., Science Europe Association and other research centres and institutes in Europe and throughout the world;
- Guidelines for applicants and evaluators, including searches of European Commission databases of funded projects;
- Grey literature from relevant evaluation bodies and institutions.

A snowballing strategy was employed to identify additional sources. For instance, in cases in which the selected sources referred to specific projects, the search for data was extended to include project reports and other available online data.

The review focused on eight disciplinary fields: Economics and Business; Educational Sciences, Media, and Communication; Humanities; Law; Life Sciences; Political Science; Psychology; and Sociology and Socio-economic Geography. Numerous combinations of keywords were employed as search terms to detect the impact of research; these terms were also applied to search key research evaluation journals. The analysis covered the period 2006–12 to coincide with the European Union’s Sixth and Seventh Framework programmes. Some key pieces of literature published before 2006 and after 2012 were also included to describe the evolution of the concepts of and approaches to evaluating the impact of SSH research. To handle the extensive range of literature, different teams scanned
the different disciplinary areas and independently identified important literature in this area. For these studies, the findings of the review were shared using standardized grids, which were presented as templates to annotate the studies.

3.1 Data analysis
A total of 288 grids were completed for the literature reviewed; two types of information were recorded: one dealing with approaches to the evaluation of the impact of SSH research, and one documenting examples of SSH research that had achieved impact (scientific, social, political). In this way we could, on the one hand, understand the new approaches and tools for evaluation methods and instruments the literature produced; and on the other hand, understand the capability of the observed approaches to properly assess the achievement of an impact.

Several limitations should be acknowledged. First, using the WoS and Scopus database and the snowball strategy, journal papers account for 95% of the reviewed literature (233 of the 275 publications that were surveyed include articles that were published between 2009 and 2012). Secondly, scientific production in the social sciences tends to be more concentrated in journal articles, and journal articles comprise a significant part of the humanities and law; thus, the latter fields are less well-represented than other fields in this review. Thirdly, the capacity to trace research outputs which are neither publicly available nor have been cited by other publications is also limited. Last, the English-language output is overrepresented, and literature written in national languages (other than English) only appears in the case of studies that have received citations.

The selected journal papers were located in 172 scholarly journals, which encompassed the entire range of SSH. These papers were not concentrated in particular core journals, with the exception of Research Evaluation, which provided 40 articles for review, followed by American Psychologist (10) and Scientometrics (7). The remaining literature included a small number of working and discussion papers (5), book chapters (3), a book (1), a doctoral dissertation (1), and “hidden” pieces of literature in the form of EU FP6 or FP7 project documents (3).

4. Scientific impact of SSH research
The debate on scientific impact has a large place in the literature on SSH research; in the past 10 years, it was mainly pushed by the advent of national ex post research assessments, and by the importance that the use of metrics gained in impact evaluation. In this respect, the value of bibliometric indicators was highlighted for STEM disciplines as more objective and less costly than other methods, but the possibility of applying these types of indicators to SSH research was highly questioned.

4.1 Bibliometrics, scientometrics, informetrics and other metrics in STEM research
The scientific impact of STEM research on the policy agenda has existed since the emergence of ‘Big Science’ after the Second World War (Price, 1963). The growth of science, the need to monitor (public) spending, and the recent shift to a knowledge-based economy caused the growth of the specialized scientific discipline of bibliometrics, scientometrics, and informetrics (De Bellis 2009). The literature is dominated by quantitative, bibliometric approaches to assess the scientific impact of research, including the use of the journal impact factor (a measure that is based on the average number of citations to articles in a specific journal) and other citation-based methods (Garfield 2006). Traditionally the measurement of scientific impact focused on publications (Scharnhorst and Garfield 2010). Increasingly, we observe the tendency to focus on individual authors as the unit of analysis (Wouters and Costas 2012). A new indicator that has gained significant attention is the h-index, which was proposed by Hirsch (2005). Tibor Braun and colleagues proposed to employ Hirsch-type indexes as useful complements to journal impact factors and to evaluate the scientific impact of research (Braun, Glänzel and Schubert 2006).

Despite these efforts, scholars in STEM disciplines have always questioned the extent to which scientific impact, measured by numbers of citations, reflects the ‘quality’ or ‘importance’ of a single journal paper or a body of scientific work. New ideas in technological innovation and instruments tend to emerge at the boundaries of scientific fields led by atypical researchers, who may never achieve recognition from their academic peers (Joerges and Shinn 2001). However, the fascination with numbers and simple data is still alive. Simple measures, such as the journal impact factor, which produce one number, are easy to apply and are attractive for many organizations that address evaluations of scientific impact. This simplicity belies the contested nature of the application of these measures (Glänzel and Moed 2002; Leydesdorff, Hammarfelt and Salah 2011). Therefore, in scientometrics, a debate about the validity of different indicators and the continuous development of new indicators is underway. One example is the Scimago Journal Rank, which is a citation impact index that considers the relative prestige of journals that cite a particular journal paper (González-Pereira, Guerrero-Bote and Moya-Arenas 2010). Thus, current metric-based evaluation practices are not without dispute, even for the natural sciences, among those that are subject to evaluation (Blockmans, Engwall and Weaire 2014), and among those that develop metrics (Hicks et al. 2015). Criticisms deal with computation of indicators and with the reliability of citations as a proxy of scientific impact.

In the mid-1980s, changes in scholarly communication and practices, which are informed by open-access principles, gained attention from epistemic communities and research institutions, and new indicators were developed based on the Web: web indicators, webometrics, cybermetrics, and altmetrics (Borgman 1990, 2007), which were supposed to complement citations to understand scientific impact of research outputs, attempting to measure the circulation and use of the research outputs within the scholars’ community. One method for ordering webometrics is a timeline of their appearance that start from calculations about the use of the Web in scholarly communication: web indicators, webometrics, cybermetrics (Scharnhorst, Wouters and van den Besselaar 2006); Web 2.0—user-generated content and the emergence of altmetrics (Priem et al. 2010; Bornmann 2014); and the Semantic web—automatically generated impact stories (see https://impactstory.org/).2

4.2 The use of metrics for assessing scientific impact of SSH research
Do metrics for measuring scientific impact works in the case of SSH research? There are different answers to this question.

Perspectives range from the idea that SSH disciplines are less scientifically developed and that existing metrics will become a better fit as they mature, to the viewpoint that the scientific impact of SSH
research cannot be captured by blunt metrics and can only be assessed by peer review (Donovan 2007; Bastow, Dunleavy and Tinkler 2014). Hicks (2004) noted the existence of four literature in social sciences: international journal articles, books, national journals, and non-scholarly publications, and despite the movement towards academics privileging the first type of publication, the importance of the other types of literature remained high.

A recent review on evaluation practices indicated that several authors outline bibliometrics in SS as one resource among many for scientific impact assessment, which can provide better results when used in combination with other metrics and information sources than when it is used as a separate tool (de Rijcke et al. 2016). This evidence raises the issue of selecting the most suitable mixed method for impact assessment. Conversely, bibliometrics do not emerge as an advantage for the assessment of the impact of humanities research. However, specific cases, such as psychology and linguistics, have a consolidated arena of relevant indexed journals in the fields.

Notwithstanding the aforementioned evidence, the majority of discussions occupy a middle ground and are dependent on bibliometrics but seek alternative techniques that are more suited to the production and consumption of SSH research, overcoming the most important limitations, such as the different citation behaviour of SSH when compared with natural sciences (Hammarfelt 2014), the different types of outputs (Hicks and Wang 2009; Torres-Salinas et al. 2013), the heterogeneity of the audience (scholars from international or national arena, non-scholarly audience) to which many research outputs are oriented (Hammarfelt 2012) and the inadequate coverage of the existing data sets (Archambault et al. 2006; Peric et al. 2013). The issue of building a comprehensive SSH database that encompasses domestic publications has also been explored by scholars’ literature (Hicks and Wang 2009; Sivertsen and Larsen 2012), and within the ESF Scoping Project, pointing out needs and recommendations to implement it (Ochner, Hug and Daniel 2016). Other results show that the ‘selectivity of journals in their choice of papers for publication’ and ‘journal diffusion’ are sensitive and useful indicators to measure the impact of scholarly journals in the humanities (De Marchi and Lorenzetti 2016). Lepori and Probst (2009) employed a novel data gathering and analysis technique to map a heterogeneous social science field (communication studies) in a culturally, socio-political, and linguistically diverse country (Switzerland), which combined the use of data that were captured from CVs and WoS indicators.

Some scholars from SSH have also recommended the use of alternative statistics, such as using Google Scholar, to capture citations that appear in both articles and books (Jacobs 2011; Prins et al. 2016). Others suggest that understanding the extent of the scientific impact of research, especially in SSH, may take many years due to long time-lags in expected citation patterns (Priem et al. 2010), thus the use of altmetrics and similar tools to create real-time inputs about how an article or a research report is being utilized could be useful (cut/paste activities, citations in media reports, online newspapers, peer-review discussions, and blogs). These webometric indicators, such as article usage data (HTML views and PDF downloads), should also be considered in the research evaluation process. However, other scholars have pointed out that the use of altmetrics in SSH produces the same advantages for other fields of science, having the same drawbacks and shortcomings as bibliometric data (Mohammadi and Thelwall 2014).

In sum, notwithstanding the efforts to use WoS data and scientometric techniques to assess the scientific impact of SSH research and the transformation of some disciplinary fields, the analysis of the literature identified many shortcomings in the proposed methods and solutions, which indicate that impact evaluations based on bibliometric resources generally underestimate the value of the SSH research outputs (Bastow, Dunleavy and Tinkler 2014). Alternative metrics, methods, and data sources are being increasingly explored to understand their potential as an alternative to bibliometrics for the scientific impact assessment of SSH research. Scholars therefore have expressed interest in the new developments to understand how far they can contribute to the long-term assessment of the impact in SSH (Ochner, Hug and Daniel 2016), pointing out the need to engage with scholars in the fields examined to construct appropriate indicators (Nederhof 2006; KNAW 2011).

5. Social impact of social sciences and humanities research

Despite the uncertainties related to properly defining social impact, there is general agreement in the literature that social impact is the change or the influence that research can have on society. The most debated problem is how this change takes place.

The literature on STEM highlights a variety of processes that research outputs follow before they can produce an impact on society. For instance, in Australia’s Research Quality Framework, definitions of research impact were co-produced with the research community and were defined as ‘adding to the social, economic, natural, and cultural capital of the nation’ (Donovan 2008: 54). Recent evidence coming from the 2014 Research Excellence Framework assessment of research impact in the UK show that social impact is defined as a change or a difference—positive or negative, produced by research (Samuel and Derrick 2015). Weinberg and colleagues (2014) identified the effect of science funding on short-term economic activity. The authors concluded that scientific activity has an economic impact on society by identifying the number of people who are directly employed in the research and the products and goods purchased by scientific institutions. In this respect, a large consensus suggests that social/societal effects of (social) research may not only exhibit a positive nature (‘benefits’) but also exhibit a negative nature and have disadvantageous consequences.

Theoretical advances in the conceptualization of social impact have affected evaluation methodologies and indicators. In our review, we find both ex ante evaluations of research projects concerning possible social impacts and ex post evaluations that monitor the impact of research (Holbrook and Frodeman 2011; Bornmann 2013; Social Sciences and Humanities Scientific Committees 2013). Two major groups of methods are distinguished: qualitative methods (including peer review, case studies, and surveys) and quantitative methods (development and use of statistical indicators and, in certain fields, advanced mathematical models such as econometric models).1

In SSH research, because shortcomings affect the use of indicators, successful practices for assessing impact are generally considered to be those that combine or integrate narratives with relevant qualitative and complementary quantitative indicators to grasp the multidimensional and contextual nature of complex societal phenomena (Spaanen, van Drooge and Sylvain 1993; Gable and 1998; Evaluating Research in Context 2010; Schmoch et al. 2010; de Jong et al. 2011; Donovan 2011; Penfield et al. 2014). Assessment methods should focus on process rather than on results,
which allows us ‘to identify how relevant research is conducted and the processes by which it is applied, or not’ (Molas-Gallart and Tang 2011).

Bastow and colleagues (2014) discuss a range of types of impacts of social scientists via engagement with business, government, the third sector, and the public via the media. Where types of engagement can be identified, the authors conclude that an assessment of the impacts of these activities is difficult. Lam (2011) has sought to identify the types of impact of research based on the attitudes of academics towards impact, the nature of the interactions between researchers and users, and the processes of using research to inform policymaking. Literature on research utilization discusses a number of models of researcher–user interactions in SSH, which focus on the extent to which the research is led by the researcher, by the user, or based on an interactive process (Amara, Ouimet and Landry 2004).

Several specific, combined, or integrated social impact tools have been developed encompassing both social impact and political impact, whose purpose is to observe how the actors involved in the knowledge production (scholars, policy makers, beneficiaries, stakeholders) interact and communicate, and how far these interactions are likely to produce a change. Table 1 summarizes few examples.

The tools in Table 1 clearly demonstrate efforts to make central the consideration of differences existing between disciplinary fields and the specificities of SSH research. In this respect, they represent a step forward in understanding hidden transformations produced within science and society—either positive or negative—during the research process and after research outputs are produced, in delivering impact, and disentangling the effects of the process of knowledge production, rather than only concentrating on impact in relation to the final outputs. Moreover, both the exclusionary and transformative dimensions of CCM (see Section 3) are likely to be included in the impact assessment.

### 6. Political impact of social sciences and humanities research

The debate about the political impact of SSH research is held not only in social and academic fora but also as part of the political research agenda (Meagher, Lyall and Nutley 2008; Lemay and Sá, 2012). In this review, we discuss the identified venues by which political impact is enhanced, which involve how researchers perform and communicate their research findings and how policy makers use scientific knowledge to inform their decisions. Among these mechanisms, ways in which these two worlds interact, how research agendas are policy-oriented, and the processes of co-creation are included.

#### 6.1 Relationships between science and policy

A body of literature has been dedicated to the study of the relationship between research and politics. Boaz and Ashby (2003) have highlighted the need for changes in traditional research assessments by creating mechanisms that can be applied to identify how research generates findings that can be usefully reported to inform politics and practice. We also need to learn how policy makers use evidence from the social sciences in their practices to address social problems.
According to Sanderson (2009), better contexts can be constructed and are needed to enhance an appropriate process for policymaking. The literature also highlights that political impact is difficult to attribute to a specific research project if both researchers and players outside the research system do not participate in impact assessment (Rymer 2011). They can achieve this by producing evidence briefings that are based on systematic reviews (Chambers et al. 2012) or by participating in advisory committees on legal practice and policy (de Jong et al. 2011).

To understand the processes and actors behind successful policymaking that applies evidence from scientific research, some authors have emphasized exploring ‘productive interactions’ (see Section 5). Similarly, the role of different stakeholders in research has been the focus of many studies that aim to describe the most effective processes in translating evidence into political impact while considering occasional or structured partnerships among stakeholders in the scientific research process (de Jong et al. 2011; Wehrens, Bekker and Bal 2012).

In recent years, the number of problem-oriented or policy-oriented research calls has increased in Europe. Scholars often remark that traditional indicators do not sufficiently measure policy-relevant effects when assessing the political impact of this type of research as they relate to traditional modes of knowledge production, known as Mode 1 (Gibbons et al. 1994). They do not consider how research contributes to ameliorating the problems that societies face or how policymakers use evidence. Erno-Kjolhede and Hansson (2011) conceptualized this type of policy-oriented research as Mode 2 research, i.e., transdisciplinary collaborative modes of knowledge production that is oriented towards policy and society, and highlighted the need to construct new indicators—Mode 2 indicators—to better monitor the research impact.

6.2 Co-production of research and research impacts

Although the main focus of the literature is on barriers to achieve political impact, some authors also point out how the co-production of research between academics and policymakers can facilitate research impact. Duijn, Rijneveld and van Hulst (2010) investigated the co-production of research between academics and policymakers, particularly in terms of negotiating complex governance processes. They believed that ‘if public managers and policy-makers become more reflective and researchers more action-oriented, they can meet in joint enquiry’ (Duijn, Rijneveld and van Hulst 2010: 228); thus, they championed the idea of a ‘community of inquiry’ located ‘in the middle between science and practice’ and where social scientists and practitioners can ‘co-produce knowledge to cope with practical challenges’ (Duijn, Rijneveld and van Hulst 2010: 230–32), a condition that is supposed to overcome the potential negative effect of policy makers that seek to reject research that does not fit with their preconceived needs. O’Hare, Coaffee and Hawkinsworth (2010) highlighted the negotiated context of co-produced research and introduced the idea of academics and practitioners working together as ‘critical friends’ to ‘negotiate clear independence’ (O’Hare, Coaffee and Hawkinsworth 2010: 246).

Cotterill and Richardson (2010) assessed the benefits of co-produced research with local government as a research partner, using randomized control trials. They reported a series of local-level experiments that are co-produced with policymakers and public service providers, including (1) to evaluate the promotion of household recycling participation in 6,580 households; and (2) to evaluate the impact of school-based education on the environmental attitudes and behaviours of 715 primary school students and their families in 27 primary schools. In terms of co-production, the authors concluded that ‘partners want to have equal say over the research methodology, and negotiations cover both the research and the intervention’ and as the ‘collective nature of civic interventions can militate against individual randomization’ researchers can encounter ‘ethical and moral objections from principled public service practitioners’ (Cotterill and Richardson 2010: 161).

From the perspective of research management from within the UK’s Economic and Social Research Council (ESRC), Armstrong and Alsop (2010) suggest that both ex ante evaluation criteria and ex post evaluation criteria should rely on a conceptual model that includes ‘the crucial role of co-production in achieving impact’ as the ESRC’s impact evaluation work has demonstrated that ‘sustained involvement of [non-academic research] users is one of the most important determinants of policy impact’ (Armstrong and Alsop 2010: 209–10). They argue that the effective co-production of research entails that research end users should be ‘involved throughout the research process, from agenda-setting, through design, fieldwork and communication of outcomes’ (Armstrong and Alsop 2010: 209).

However, less attention has been placed on studying how these partnerships include the voices of the most vulnerable end users throughout the entire research process. Some articles provide evidence of these successful actions, which are designed via dialogue among scientists, civil society, and policy makers (Flecha and Soler 2014). When these successful actions address targets in the political agenda and provide evidence of overcoming inequality (for example, by reducing school dropout or creating sustainable employment), transfer into policy tends to be smooth and attributable to a specific research project. In some examples, such as the case of the inclusion of ethnic minorities, these partnerships can shape the practice of policymaking in discussing and evaluating action plans for social inclusion (Munté, Serradell and Sordé 2011).

However, a clear gap emerged in the analysis, which refers to the lack of investigation of the possible negative impacts of engagement on research agendas, and the lack of willingness of policy makers to use evidence of impact to become more reflexive.

7. Discussion

We now summarize the main findings of the literature review presented in the article, especially the exclusionary and transformative dimensions of CCM (see Section 3), and what inhibits or allows for various types of research impact to occur.

Regarding scientific impact in SSH, scholars focused on bibliometric analyses, indicators, and tools that are related to publications, to understand the extent to which these can be applied to SSH research; the limitations that affect metrics for SSH are not yet solved and a clear knowledge gap still exists. The gap also refers to the strong orientation of the scholars’ efforts towards considering scientific impact as a change produced by a single (or a combination of) piece(s) of research, with a limited interest in deepening conditions of the research processes contributing to generating an impact in the interested fields (Morton 2015).

Generally speaking, it is recognized that changes in scholarly communication are likely to transform and improve our capability to understand the scientific impact of research outputs and surpass
the simple paper publication. Although new digital traces will inspire the search for new automatic metrics, understanding of the limits and possible drawbacks of metrics-only approaches in SSH is increasing. In the scientific discourse, we strive for a subtler use of indicators and its combination with qualitative methods of evaluation. The latter extends from traditional peer review to tracing narratives and success stories that are both supported by automatic means. If such an effect exists, then the role of time and timescales in deploying aspects of the impact should be considered.

In both political and social impact of SSH research and, to some extent, scientific impact, we observed an increasing trend towards responding to the demand to create new opportunities for participation and public engagement of researchers and stakeholders. Creating shared dialogical spaces and promoting processes of co-production of research between academics and policy makers are assessed as promising practices that are likely to create greater political impact, and in some cases (not all), social impact.¹

Despite significant divergence, some common elements are recognized in the reviewed literature. In terms of conceptualization, political impact refers to the transfer of research findings to the political sphere to inform decision-making or policy design, and social impact refers to the extent to which an action from a policy or a civil society-led action has actually contributed to improve identified social challenges.

Another important aspect is whether researchers generate interventions based on research findings and provide evidence on resulting social improvements, or whether researchers identify actions that have a positive impact on society and analyse their features to create possibilities for transferability. Two different perspectives emerged in the review regarding impact assessment. The first is building indicators and metrics to ‘measure’ impact, and assumes impact as a magnitude of forward progress. The second assesses the extent to which conditions for an impact to occur have been created and mobilized, and assumes that impact is an emerging property, which depends on later choices and events beyond the scholars’ immediate control. The literature shows that both avenues are explored as far as SSH research is concerned, but the latter gained more interest and consensus that the former.

Regarding problems of attributing and identifying the political and social impacts of particular pieces of research, the literature review has demonstrated the need for additional improvements in methods, techniques, metrics, and methodologies to better grasp the impact of research in SSH fields. Despite the technical limitations, we have identified a transformation of the scientific community in being increasingly aware of not only the crucial importance of achieving these types of impacts but also their responsibility to gather evidence and information to support impact claims. For instance, evidence emerged in the literature on the contribution and impact of SSH research on policies related to social problems, such as social exclusion, gender discrimination, and other relevant social challenges (Larivière et al. 2013; Rawlings and McFarland 2011; Sordé-Martí et al. 2014), demonstrating possibilities for such data collection.

Last but not least, the analysis found that SS research was well represented in the specialized literature on political and social impacts. This finding applies to the humanities in more recent time, a delay that may be attributed to the characteristics of the epistemic communities that are included within the humanities, and are traditionally less focused on demonstrating an ‘impact’ to external stakeholders (Ochsner et al. 2013). There are also signals that the interest in SSH research on impact assessment is likely to improve in the future. For instance, the recent HERAVALE project under the FP7 noted that ‘there is evidence of a genuine commitment to A&HR, and that policymakers and the academy are inching towards a common language’ (Hazelkorn 2014: 27), and the more recent literature demonstrates important efforts of scholars to critically engage with the problem of impact in SSH research (Ochsner, Hug and Daniel 2016; Levitt et al., 2010).

8. Conclusion
The main purpose of this article was to shed light on how scholars have dealt with the problem of assessing the impact of SSH research, and whether impact assessment approaches and techniques developed for STEM disciplines can legitimately be used for SSH.

The analysis shows that scientific impact has gained a space in the literature of SSH; however, the predominant methods tend to underestimate the value of SSH research outputs because efforts fail to properly take into account the distinctive features of SSH research that differ from the natural sciences. In addition, the presence of adverse feelings of SSH scholars about quantifications and indicators (Ochner, Hug and Daniel 2016) still emerge in the analysis.

Some recent pieces of literature provide evidence that the most important and unavoidable social contributions of SSH are in providing an understanding of shared values, improving social awareness—also in an historical perspective—of our common cultural heritage, and the maintenance over the generations of the constitutive elements of our society (Small 2013). In this respect the separation between SSH and other fields is a category mistake, since all contribute to the human well-being (Bod 2013).

We have identified areas that require additional exploration in future studies. First, as social impact and political assessments are already performed in several national contexts and other initiatives with substantial differences, the need to produce systematic and comparable assessments of these processes is evident (Price and Peterson 2016).

Secondly, although each process for assessing the social impact of SSH research has different levels of development in different countries, considerable improvements in terms of identifying and analysing convergences affecting these processes are needed.

Lastly, a third area involves the investigation of why research does not achieve an envisioned impact (scientific, political, or social). The surveyed literature addressed either methodological issues that are related to the assessment of impact of SSH, or impact assessments using different methods. In the latter case, almost all studies emphasize the transformative dimension by demonstrating how impact has been achieved and how metrics and methodological approaches are likely to determine the change produced by research. Failure is unacceptable and rendered invisible, and so the exclusionary dimension does not emerge as a central item to be assessed. A possible explanation may be that scholars generally consider outputs to be publishable to represent successful positive achievements. Another explanation may be that the collective literature aims to show unintended and negative consequences of existing assessment approaches rather than searching for explanations of the lack of
impact. A further possibility is the long-term perspective of impact in SSH research, which considers impact a normal effect of research (Ochsner et al. 2013) but occurring at a time that can be very distant from the research activities and is therefore difficult to investigate. Thus, the exclusivity dimension is a topic that deserves special attention and may inform future investigations.

Funding

This study was supported by the European Union’s Seventh Framework Programme for research, technological development and demonstration (FP7/2014-2017) under grant agreement number 613202 (IMPACT-EV Evaluating the Impact and Outcomes of European SSH Research).

Notes

1. Flash-it is a project funded under the European Union’s Seventh Framework Programme that seeks, among other things, to standardize, analyze, synthesize, and disseminate research results by creating a SSH network and the technological tools necessary to facilitate this.

2. These developments also affect the analysis of SSH research impact. A pioneer in the area of open access, which also explores altmetrics, is the Public Library of Science PLOS Medicine Editors, 2006. The PLOS explores tools to track the post-publication reception of any research (Fenner 2014); this process has also been promoted by SSH scholars to generate Open Access initiatives, such as the Public Knowledge Project (MacGregor, Stranack and Willinsky 2014).

4. The Mode 1 and Mode 2 concepts originally come from Gibbons et al. (1994).

5. One recent example from the impact assessment of the Arts and Humanities Research Council in UK, in which the impact of Arts and Humanities Research was assessed regarding contributions to the development of creative industries, cultural engagement, new skills enhancement, and collaborative opportunities to sustain the emergence of new ideas and perspectives (AHRC 2015).
