Running title: Methylocystis bryophila sp. nov.
A new species is proposed for two facultatively methanotrophic representatives of the genus *Methylocystis*, strains H2s$^T$ and S284, which were isolated from an acidic (pH 4.3) *Sphagnum* peat bog lake (Teufelssee, Germany) and an acidic (pH 3.8) peat bog (European North Russia), respectively. Cells of strains H2s$^T$ and S284 are aerobic, Gram-negative, non-motile, curved coccoids or short rods that contain an intracytoplasmic membrane system typical of type II methanotrophs. They possess both a soluble and a particulate methane monooxygenase (MMO); the latter is represented by two isozymes, pMMO and pMMO2. The preferred growth substrates are methane and methanol. In the absence of C1 substrates, however, these methanotrophs are capable of slow growth on acetate.

Atmospheric nitrogen is fixed by means of an aero-tolerant nitrogenase. Strains H2s$^T$ and S284 grow between pH 4.2 and 7.6 (optimum pH 6.0-6.5), and at temperatures between 8 and 37°C (optimum 25-30°C). The major fatty acids are C18:1$\omega_8c$, C18:1$\omega_7c$, and C16:1$\omega_7c$; the major quinone is Q-8. The DNA G+C content is 62.0-62.3 mol%. Strains H2s$^T$ and S284 share identical 16S rRNA gene sequences, which displayed 96.6-97.3% similarity to sequences of other taxonomically characterized members of the genus *Methylocystis*. Therefore, strains H2s$^T$ and S284 are classified as a novel species, for which the name *Methylocystis bryophila* sp. nov. is proposed. Strain H2s$^T$ (=DSMZ 21852$^T$ = VKM B-2545$^T$) is the type strain of *Methylocystis bryophila*.

**Keywords:** *Methylocystis bryophila* sp. nov., facultative methanotrophy, acetate-utilizing methanotroph.

The GenBank/EMBL/DDBJ accession numbers for the 16S rRNA gene sequence and the partial sequences of the *mmoX*, *pmoA*, *pmoA2*, and *nifH* genes of *Methylocystis bryophila* H2s$^T$ are FN422003-FN422005 and HE798545-HE798546, respectively.
The genus *Methylocystis* is one of the five genera which were included in the first taxonomic framework of methanotrophic bacteria created by Whittenbury and colleagues (1970). This genus belongs to the class *Alphaproteobacteria*, the family *Methylocystaceae*, and encompasses strictly aerobic utilizers of C1 compounds with type II intracytoplasmic membranes (ICM) and the serine pathway of carbon assimilation (Bowman et al., 1993; Bowman, 2000). At present, the genus *Methylocystis* includes five validly described species: *M. parvus*, *M. echinoides* (Bowman et al., 1993), *M. rosea* (Wartiainen et al., 2006), *M. hirsuta* (Lindner et al., 2007), and *M. heyeri* (Dedysh et al., 2007).

For a long time, representatives of the genus *Methylocystis* were considered to be obligately methanotrophic bacteria, which are incapable of growth on multicarbon substrates. Recently, however, two novel facultatively methanotrophic members of this genus, strains H2sᵀ and SB2, were isolated from the acidic *Sphagnum* peat bog lake Teufelssee in northeastern Germany and a spring bog in southeast Michigan (Belova et al., 2011; Im et al., 2011). Both isolates demonstrated a clear preference for growth on methane but were also able to grow slowly on acetate or ethanol in the absence of methane. No growth occurred on other multicarbon substrates. 16S rRNA genes of strains H2sᵀ and SB2 displayed only 96% sequence similarity. Apparently, these isolates represented two different and potentially novel species of the genus *Methylocystis*. Strain SB2 was most closely related to *Methylocystis rosea* SV97ᵀ and *Methylocystis echinoides* IMET 10491ᵀ (98% 16S rRNA gene similarity to both strains) (Im et al., 2011), while strain H2sᵀ showed the highest 16S rRNA gene sequence similarity (99.5%) with the taxonomically uncharacterized *Methylocystis* sp. strain F10V2a, which was isolated from the surface sediment of the dystrophic peat bog lake Fuchskuhle, northeastern Germany (Heyer et al., 2002). Strain F10V2a was characterized with regard to its fatty acid composition (Bodelier et al., 2009) and the presence of *pmoA2* gene encoding the β-subunit of particulate methane monooxygenase that oxidizes methane at low mixing ratios (pMMO2) (Tchawa Yimga et al., 2003; Baani & Liesack, 2008). This strain, however, has been lost and could not be used for the comparative analysis.
Lately, we obtained one additional, strain H2s<sup>T</sup>–like methanotroph, designated strain S284. It was isolated from acidic (pH 3.8) peat sampled in August 2008 at a depth of 5-10 cm of the *Sphagnum* peat bog Staroselsky Moss, Central Forest Reserve, Tver region, European North Russia (56°58'N, 32°30'E). Strains H2s<sup>T</sup> and S284 shared identical 16S rRNA gene sequences and displayed similar phenotypic traits. Most importantly, strain S284 was also capable of slow growth on acetate. This study was initiated in order to characterize the two novel isolates of facultatively methanotrophic *Methylocystis* spp. and to determine their taxonomic position.

Strains H2s<sup>T</sup> and S284 were maintained on agar and liquid medium M2 containing (in grams per litre distilled water) KNO<sub>3</sub>, 0.25; KH<sub>2</sub>PO<sub>4</sub>, 0.1; MgSO<sub>4</sub> × 7H<sub>2</sub>O, 0.05; CaCl<sub>2</sub> × 2H<sub>2</sub>O, 0.01; and NaCl, 0.02, with the addition of 0.1% (by volume) of a trace elements stock solution containing (in grams per litre) EDTA, 5; FeSO<sub>4</sub> × 7H<sub>2</sub>O, 2; ZnSO<sub>4</sub> × 7H<sub>2</sub>O, 0.1; MnCl<sub>2</sub> × 4H<sub>2</sub>O, 0.03; CoCl<sub>2</sub> × 6H<sub>2</sub>O, 0.2; CuCl<sub>2</sub> × 5H<sub>2</sub>O, 0.1; NiCl<sub>2</sub> × 6H<sub>2</sub>O, 0.02, and Na<sub>2</sub>MoO<sub>4</sub>, 0.03. The medium pH was 5.5. For growth in liquid media, 500 ml screw-cap serum bottles were used with a headspace/liquid space ratio of 4:1. After inoculation, the bottles were sealed with silicone rubber septa, and methane was added aseptically using a syringe equipped with a disposable filter (0.22 µm) to achieve a 10-20% mixing ratio in the headspace. Bottles were incubated on a rotary shaker (120 rpm) at 24°C. Purity tests were performed as described by Belova *et al.* (2011) and included: i) examinations using phase-contrast and electron microscopy, ii) plating on complex organic media, iii) DGGE analysis of 16S rRNA gene amplicons and iv) whole-cell hybridization with fluorescently labeled group- and species-specific probes M450 and Mcyst-1273.

Morphological observations and cell size measurements were made with a Zeiss Axioplan 2 microscope and Axiovision 4.2 software (Carl Zeiss, Germany). For preparation of ultrathin sections, cells were pre-fixed with 1.5% (wt/vol) glutaraldehyde in 0.05M cacodylate buffer (pH 6.5) for 1 h at 4°C and then fixed in 1% (wt/vol) OsO<sub>4</sub> in the same buffer for 4 h at 20°C. After dehydration in an ethanol series, the samples were embedded in a Spurr epoxy resin. Thin sections were cut on an LKB-4800 microtome, mounted on copper grids covered with Formvar film, contrasted with 3% (wt/vol) uranyl acetate in 70% (vol/vol) ethanol for 30 min, and then
stained with lead citrate (Reynolds, 1963) at 20°C for 4–5 min. The preparations were examined in a JEM-100C (JEOL, Japan) electron microscope at an 80 kV accelerating voltage. Physiological tests were carried out in liquid medium M2 with methane. Growth of strains was monitored by measuring OD$_{410}$ for 2 weeks under a variety of conditions, including temperatures of 2-37°C, pH 3.9-8.0 and NaCl concentrations of 0-3.0 % (wt/vol). The following carbon sources (each at a concentration of 0.05%, w/v) were examined to determine the range of substrates that could be utilized by strains H2s$^\top$ and S284: ethanol, formate, formaldehyde, glucose, fructose, arabinose, lactose, sucrose, maltose, galactose, acetate, citrate, oxalate, malate, pyruvate and succinate. The capacity to utilize methanol at concentrations from 0.01 to 2% (vol/vol) was determined in liquid medium M2 supplemented with CH$_3$OH. Nitrogen sources were tested by replacing KNO$_3$ in medium M2 with 0.05% (wt/vol) (NH$_4$)$_2$SO$_4$, NaNO$_2$, glycine, L-alanine, L-serine, L-threonine, L-valine, L-leucine, L-isoleucine, L-proline, L-cysteine, L-methionine, L-glutamine, L-asparagine, L-histidine, L-lysine, L-ornithine or yeast extract. In all substrate utilization tests, growth was examined after 1 month of incubation and confirmed by comparison with the respective negative control.

Cell biomass for fatty acid and isoprenoid quinone analyses as well as for DNA extraction was obtained from batch cultures grown in liquid medium M2 at 24°C up to the late exponential phase (7 days). Fatty acid analysis was performed as described for Methylocystis heyeri (Dedysh et al., 2007). Since fatty acid composition was not reported for Methylocystis hirsuta in the original description (Lindner et al., 2007), we determined it in our study. Isoprenoid quinones were extracted according to Collins (1985) and analyzed using tandem-type mass spectrometer LCQ ADVANTAGE MAX and ionization mass spectrometer Finnigan Mat 8430. The DNA base composition of strains H2s$^\top$ and S284 was determined by thermal denaturation (Owen et al., 1969) using a Unicam SP1800 spectrophotometer (UK) at a heating rate of 0.5 °C min$^\mathbf{-1}$. The DNA of Escherichia coli K-12 was used as a standard. PCR-mediated amplifications and sequencing of the nearly-complete 16S rRNA gene and partial fragments of the pmoA and mmoX genes from DNA of strain S284 were performed as described for strain H2s$^\top$ (Belova et al.,
In addition, partial fragments of *nifH* gene from DNA of both strains were amplified and sequenced using the primers and the reaction conditions described by Dedysh *et al.* (2004). Phylogenetic analysis was carried out using the ARB program package (Ludwig *et al.*, 2004). The trees were constructed using distance-based (neighbor-joining), maximum-likelihood (DNAml), and maximum-parsimony methods. The significance levels of interior branch points obtained in neighbor-joining analysis were determined by bootstrap analysis (1000 data resamplings) using PHYLIP (Felsenstein, 1989).

Strains H2s^T^ and S284 were represented by Gram-negative, non-motile, curved coccioids or short rods (Fig. 1A). Cells were 0.9-1.4 μm wide by 1.8-3.4 μm long, occurred singly, did not form rosettes and reproduced by normal cell division. Analysis of thin sections of cells grown on methane revealed a well-developed system of intracytoplasmic membranes (ICM) aligned parallel to the cytoplasmic membrane (Fig. 1B). This ICM arrangement is typical of members of the *Methylosinus*/*Methylocystis* group (Whittenbury *et al.*, 1970; Bowman, 2000). Some cells in 2-3-old batch cultures contained granules of poly-β-hydroxybutyrate. On solid M2 medium, strains H2s^T^ and S284 formed small (1-3 mm in diameter), raised, white or cream colonies with an entire edge and a smooth surface. Liquid cultures of both strains displayed white turbidity.

Methane was the preferred growth substrate of strains H2s^T^ and S284. The specific growth rate of these bacteria in liquid culture with CH₄ (10%, vol/vol) under optimal growth conditions (see below) was 0.06 h⁻¹ (equivalent to a doubling time of 11.5 h). Maximal OD₄₁₀ of methane-grown cultures of strains H2s^T^ and S284 ranged from 0.9 to 1.2. Methanol supported growth only at concentrations below 0.15% (vol/vol). Growth factors were not required. No growth occurred on formate, formaldehyde, glucose, fructose, arabinose, lactose, maltose, raffinose, sorbitol, mannitol, inositol, citrate, oxalate, malate, succinate, galacturonate, alanine, asparagine, glutamine, serine, glycine, pectin, or xylan. Nearly undetectable, trace growth (up to OD₄₁₀ of 0.05-0.06 after 1.5 months of incubation) occurred on pyruvate and ethanol. However, clearly detectable albeit slow growth with the specific growth rate of 0.006-0.007 h⁻¹ (equivalent to a doubling time of 100-115 h) was observed on acetate (see Belova *et al.*, 2011). The OD₄₁₀ of
acetate-grown cultures reached 0.25-0.35 following 3-4 weeks of incubation (comparing to
OD\textsubscript{410} 0.02 in control). Both strains were able to survive multiple (4-5) transfers on a medium
containing acetate. The pathway by which acetate is assimilated by these methanotrophs is still
unclear, but it has been hypothesized that facultative \textit{Methylocystis} species may utilize the
coupled ethylmalonyl-CoA/serine cycle when grown on acetate (Semrau \textit{et al.}, 2011).

Strains H2s\textsuperscript{T} and S284 utilized ammonium salts, nitrates, yeast extract, L-asparagine, L-
alanine, L-serine, L-proline, L-isoleucine, L-glutamine and L-cysteine (0.05% w/v) as nitrogen
sources (OD\textsubscript{410} of 0.2-1.0), but were also capable of weak growth in nitrogen-free liquid media
(OD\textsubscript{410} up to 0.15 after 2 weeks of incubation). Partial \textit{nifH} gene sequences determined for
strains H2s\textsuperscript{T} and S284 (accession numbers HE798545 and HE798549) were highly similar
(98.8%) to each other and displayed highest (91-92.0%) nucleotide sequence identity to the
corresponding gene fragments from members of the genera \textit{Bradyrhizobium} and \textit{Methylocystis}.

Strain H2s\textsuperscript{T} grew in the pH range 4.4-7.6, while strain S284 was slightly more
acidotolerant (pH range 4.2-7.6). Both isolates showed optimal growth at pH 6.0-6.5. This
optimum and range are similar to those reported for another peat-inhabiting member of the genus
\textit{Methylocystis}, \textit{M. heyeri} (Dedysh \textit{et al.}, 2007). The temperature range for growth was 8-37\textdegree C,
with the optimum at 25-30\textdegree C. Both strains were highly sensitive to NaCl. Growth of strain H2s\textsuperscript{T}
was inhibited in the presence of 0.4% NaCl (w/v), while 0.2% NaCl completely inhibited growth
of strain S284.

The major component of the PLFA (\textit{polar lipid derived fatty acids}) profile in cells of
strains H2s\textsuperscript{T} and S284 was C18:1\textsubscript{ω}8c fatty acid (Table 1). This fatty acid is commonly present in
all currently known members of the genus \textit{Methylocystis} (Bodelier \textit{et al.}, 2009). This PLFA is
also present in representatives of the genus \textit{Methylosinus}. What distinguishes members of the
genus \textit{Methylocystis} from all other currently described methanotrophs is the presence of the
PLFA’s C18:2\textsubscript{ω}7c,12c and/or C18:2\textsubscript{ω}6c,12c. Among the described \textit{Methylocystis} species, the
absence of C18:2\textsubscript{ω}6c,12c in strains H2s\textsuperscript{T} and S284 differentiates them from \textit{M. echnoides}, \textit{M.}
\textit{parvus} and \textit{M. hirsuta}. \textit{M. heyeri} and \textit{M. rosea} deviate from all other \textit{Methylocystis} species by
the complete absence of C18:2\omega 7c,12c and or C18:2\omega 6c,12c. Another PLFA feature that
distinguishes strains H2s\textsuperscript{T} and S284 from other *Methylocystis* species is the high amount of
C16:1\omega 7c and C16:0.

Comparative sequence analysis of the 16S rRNA gene showed that strains H2s\textsuperscript{T} and S284
belong to the phylogenetic cluster formed by the genera *Methylocystis* and *Methylosinus* within
the *Alphaproteobacteria* (type II methanotrophs) (Fig. 2). The most closely related cultured
representative of these bacteria is the taxonomically uncharacterized *Methylocystis* sp. strain
F10V2a (99.5% sequence similarity) from the dystrophic peat bog lake Fuchskuhle (Heyer et al.,
2002). Five other phylogenetically related isolates (99-100% sequence similarity), strains M162,
M167, M169, M175, and M212 (GenBank accession numbers JN036511-JN036514 and
JN036516), were recently obtained from an acidic *Sphagnum* peat bog at the Mariapeel nature
reserve, the Netherlands (Kip et al., 2011). Since only partial (800-1100 bp) nucleotide
sequences of 16S rRNA genes were determined for these isolates, they were not included in the
tree. 16S rRNA gene sequence difference between strains H2s\textsuperscript{T} and S284 and the type strains of
other described *Methylocystis* species was 2.7-3.4%. Due to the substantial phylogenetic
divergence, strains H2s\textsuperscript{T}, S284 and F10V2a fall outside a detection scope of a genus-specific
probe for *Methylocystis* spp., Mcyst-1432 (Dedysh et al., 2003), so that an additional probe,
Mcyst-1273, was designed for specific detection of these methanotrophs (Belova et al., 2011).

Phylogenetic analysis based on fragments of the *pmoA1* gene, which encodes the β-
subunit of pMMO, revealed that strains H2s\textsuperscript{T}, S284, and F10V2a possess identical nucleotide
*pmoA1* sequences but display only 87.9-90.0% nucleotide sequence identity (or 90.7-93.4% derived amino acid sequence identity) to *pmoA1* gene fragments from other taxonomically
categorized members of the genus *Methylocystis* (Fig. 3). The presence of *pmoA2* encoding the
second type of pMMO (pMMO2) in *Methylocystis* sp. strain F10V2a was demonstrated before
with the use of primers designed to specifically target this gene (Tchawa Yimga et al., 2003). The
*pmoA2* gene sequences determined in our study for strains H2s\textsuperscript{T} and S284 were identical to that
in strain F10V2a (Fig. 3). Unexpectedly, *pmoA2* fragments were amplified from DNA of strains
H2sT and S284 using the primer combination A189f - A682b (Holmes et al., 1995), which is routinely employed for pmoA1 detection in methanotrophs. The conventional PCR carried out at the annealing temperature 50ºC with this primer combination and template DNA from strain H2sT yielded both the pmoA1 and pmoA2 gene fragments in relation 4:1. Further comparison of the PmoA2 sequences from the novel isolates with those in the public database revealed their high similarity (97.7-98.3%) to the inferred peptide sequences of pmoA clones designated P13.6, P12.12 and P12.8 (accession numbers AY080950, AY080958, AY080959), which were retrieved by means of stable isotope probing technique from an acidic forest soil incubated under 13CH4 (Radajewski et al., 2002). Apparently, these clones represent pmoA2 gene fragments from strain H2sT–like methanotrophs. Another highly similar PmoA2 sequence (accession number FR726179) was retrieved from an acidic fen in Germany (Wieczorek et al., 2011). The identity values between the PmoA2 sequences of strains H2sT, S284, and F10V2a and the PmoA2 sequences from other known alphaproteobacterial methanotrophs comprised 89.0-91.8%, respectively.

Strains H2sT, S284, and F10V2a are, therefore, the first characterized representatives of peat-inhabiting methanotrophs that possess pMMO2. The latter is responsible for oxidizing methane at low mixing ratios, even at the trace level of atmospheric methane (Baani & Liesack, 2008). Notably, high-affinity methane oxidation has earlier been detected in a Sphagnum-derived peat (Dedysh & Panikov, 1997; Wieczorek et al., 2011). Given that strain H2sT–like bacteria represent one of the dominant methanotroph populations in Sphagnum-dominated northern wetlands (Belova et al., 2011; Kip et al., 2011), their contribution to the processes of atmospheric methane consumption might have been underestimated.

The partial nucleotide sequences of the mmoX gene, encoding the α-subunit of sMMO hydroxylase, were also nearly identical in strains H2sT, S284 and Methylocystis sp. strain F10V2a, but displayed only 85.7-88.3% nucleotide sequence identity (or 93.6-95.7% derived amino acid sequence identity) to mmoX gene fragments from other members of the Methylosinus/Methylocystis group (Fig. 4). As shown in our previous study (Belova et al., 2011),...
**Emended description of the genus Methylocystis** (ex Whittenbury et al. 1970) Bowman et al. 1993

Gram-negative cells that are reniform, cocccobacillary or rod-shaped; 0.3-1.2 μm wide by 0.5-4.0 μm long. Reproduces by normal cell division. Does not form either rosettes or exospores. May form a lipid cyst. Nonmotile. Encapsulated. May accumulate poly-β-hydroxybutyrate and polyphosphate. May form spinae on cell surfaces. Contains type II intracytoplasmic membranes which are aligned parallel to the cell wall. Possess pMMO; some strains may possess sMMO. Grows at temperatures between 5 and 40ºC and at pH values between 4.5 and 9.0. Organic growth factors and NaCl are not required for growth. Aerobic chemolithotroph. Utilizes C1
compounds via the serine pathway. May utilize acetate or ethanol. No growth occurs on complex organic media. Does not contain the Benson-Calvin cycle for CO₂ fixation but contains a complete tricarboxylic acid cycle. Capable of dinitrogen fixation. Produces oxidase and catalase. All representatives possess 18:1ω₈c as the predominant PLFA; some species may also possess 16:1ω₈c as a major PLFA. In case of methanotrophic bacteria the PLFA’s C18:2ω7c,12c and or C18:2ω6c,12c have only been demonstrated to be present in the genus Methylocystis and can thus be regarded as a diagnostic lipid for this genus. The major quinone is ubiquinone 8. The DNA base composition ranges from 61.5 to 67.0 mol%. Phylogenetically belongs to the Alphaproteobacteria and is closely related to the genus Methylosinus. Methylocystis parvus is the type species.

Description of Methylocystis bryophila sp. nov.

Methylocystis bryophila (bry.o’phi.la. Gr. neut. n. bryon moss; Gr. adj. philus loving; N.L. fem adj. bryophila moss-loving intended to mean moss-associated).

Gram-negative, curved coccoids, 0.9-1.4 μm wide by 1.8-3.4 μm long. Cells occur singly, do not form rosettes. Reproduce by binary fission. Non-motile. Produce intracellular PHB granules. Cells contain a well developed, type II ICM system. Possess both pMMO and sMMO. The temperature range for growth is 8-37°C with the optimum at 25-30°C. Growth occurs between pH 4.2 and 7.6 with the optimum at pH 6.0-6.5. The preferred growth substrate is methane. Methanol is utilized at concentrations below 0.1% (vol/vol). Growth factors are not required. Capable of slow growth on acetate. Nitrogen sources are ammonium salts, nitrates, yeast extract, L-asparagine, L-alanine, L-serine, L-proline, L-isoleucine, L-glutamine and L-cysteine. Capable of N₂ fixation. NaCl inhibits growth at a concentration above 0.1% (wt/vol). The major PLFAs are C18:1ω8c, C18:1ω7c and C16:1ω7c. The major quinone is Q-8. The DNA G+C content is 62.0-62.3 mol%. Habitats are acidic wetlands. The type strain is strain H2sᵀ (= DSMZ 21852ᵀ = VKM B-2545ᵀ), which was isolated from the acidic peat bog lake Teufelssee, Northeastern Germany.
ACKNOWLEDGMENTS

This research was supported by the Program “Molecular and Cell Biology” and the Russian Fund of Basic Research (projects No 09-04-91332 and 12-04-00768). The authors want to thank Ekaterina N. Detkova for DNA G+C content determination.

FIGURE CAPTIONS

Fig. 1. (A) Phase-contrast micrograph of cells of strains H2sT grown in liquid mineral medium M2 under methane for 7 days; bar, 5 μm. (B) Electron micrograph of ultrathin section of a cell of strain H2sT; bar, 0.5 μm.

Fig. 2. 16S rRNA gene-based neighbor-joining tree showing the phylogenetic positions of strains H2sT, S284 and F10V-2a in relation to other taxonomically characterized members of the family Methylocystaceae and phylogenetically related representatives of the family Beijerinckiaceae. Bootstrap values (percentages of 1000 data resamplings) >50% are shown. Black circles indicate that the corresponding nodes were also recovered in the maximum-likelihood and maximum-parsimony trees. The type I methanotrophs Methylomicrobium album (X72777), Methylobacter luteus (AF304195), Methylomonas methanica S1 (AF304196) and Methylococcus capsulatus Texas (AJ563935) were used as an outgroup. Bar, 0.05 substitutions per nucleotide position.

Fig. 3. Neighbor-joining tree constructed based on 150 deduced amino acid sites of partial pmoA1 and pmoA2 gene sequences, showing the positions of strains H2sT, S284 and F10V2a relative to other type II methanotrophs. Bootstrap values (1000 data resamplings) >80% are shown. Black circles indicate that the corresponding nodes were also recovered in the maximum-likelihood and maximum-parsimony trees. The type I methanotrophs Methylomonas methanica (U31653), Methylobacter psychrophilus (AY945762), Methylomicrobium album (U31654), Methylocaldum tepidum (U89304), Methylocaldum szegediense (U89303), and Methylococcus capsulatus (L40804) were used as an outgroup. Bar, 0.1 substitutions per nucleotide position.

Fig. 4. Unrooted neighbor-joining tree constructed based on 328 deduced amino acid sites of partial mmoX gene sequences, showing the positions of strains H2sT and S284 relative to other sMMO-possessing type I and type II methanotrophs. Bootstrap values (1000 data resamplings)
>80% are shown. Black circles indicate that the corresponding nodes were also recovered in the maximum-likelihood and maximum-parsimony trees. Bar, 0.05 substitutions per nucleotide position.
